

Ideas-

The biggest challenge was keeping track of the websites in an order fashion using stacks. I decided to have stacks dedicated to the back button and forward button respectively. The idea is keep populating the back stack in the visitPage method that way we'd have the top - 1 to be the previous site. To get access to this previous site we'd take the top of the back stack and push it onto the forward stack. That way we take care of that -1 from top - 1. Now the top of the back is the previous website which we can equate to current\_page. And we now have a way of going back to the forward site that it came from using the forward stack. That's essentially my big high level general idea. Didn't use any resources this time around the code is built from a very rudimentary style.
